ABSTRACT. Time series of beginning-of-month water levels and rates of change of lake storage were determined for each of the Great Lakes and Lake St. Clair for 1941-1975 period. The Thiessen polygon procedure was used to compute the beginning-of-month levels because it provides more representative overall lake levels than straight averaging and requires minimum subjectivity. The effect of crustal movement on the rate of change of lake storage was investigated and found to be negligible. A gage density analysis showed good agreement between various size gage networks with the maximum deviation between networks decreasing with increasing gage density. Thiessen polygon weighting factors are presented for the current gage networks to enable future extension of the time series.

INTRODUCTION

The need for improved hydrologic data for Great Lakes water resource and scientific studies is increasing as the value of the water resources increases. This study presents a procedure to better quantify beginning-of-month water levels and rates of change in storage of each of the Great Lakes and Lake St. Clair based upon the Thiessen polygon technique. Beginning-of-month levels are necessary to compute the change in storage term of the lakes' hydrologic cycle and are also used for the calibration, verification, and application of Great Lakes water quantity and regulation models.

Previous studies such as the International Great Lakes Level Board (1973) study used straight averaging with some subjective adjustment and only a limited number of the available gages to compute lake levels and changes in storage. In this study the Thiessen polygon procedure was selected as it provides a better representative lake level than straight averaging and requires minimum subjectivity. Since 1950 the number of available water level gages has increased from 25 to 50. The initial study period was comprised of the years 1950-1970 as they contained a sufficient number of water level gages to analyze the effect of the gage density on the begin-

ning-of-month level computations. This period is also significant because it includes the high lake levels of 1952, as well as the record lows of 1964. The recommended procedure is used to develop a data base for the 1941-1975 time period as it is of the greatest current interest to researchers, engineers, and managers in the Great Lakes community.

METHODOLOGY

The beginning-of-month water levels were computed by the use of a water level gage network on the periphery of the lake. Ideally, the beginning-of-month level should represent the instantaneous level at the beginning of the month. Practically, however, representative instantaneous true water levels are difficult, if not impossible, to measure because of the effect of short-term fluctuations in wind speed and direction and changes in atmospheric pressure over very small time periods. These fluctuations could cause considerable error in computing a true instantaneous level for the lake. This error is lessened by specifying that the beginning-of-month level for each gage shall be equal to the average of the daily mean water levels of the first day of the month and the last day of the preceding month.

The computations procedure set forth by Quinn (1971) consists of applying areally weighted factors

¹GLERL Contribution No. 96.

to water levels for each gage in the network. The weighting factors were computed from Thiessen polygon networks drawn from the various water level gage networks. This is expressed mathematically as

$$L_0 = W_1 L_1 + W_2 L_2 + W_3 L_3 + \dots + W_n L_n$$

for

$$W_1 + W_2 + W_3 + \dots + W_n = 1.0$$

where

L_0 is the weighted beginning-of-month water level

L_1-L_n are the beginning-of-month levels at the various gage locations

W_1-W_n are the Thiessen polygon weighting factors for gage locations, 1 to n

n is the number of water level gages in the network.

The basic data consisted of daily mean water levels for the first and last days of the months for each water level gage in operation. These levels were computed from the gages by use of sampling rates that varied from hourly observations in the

current period to some tri-daily observations in the early portion of the study. Gage response times, which are usually less than 1 minute, are sufficient to filter out effects of wind and ship generated waves and to determine longer period lake level variations. The water level gage locations used in the study are shown in Figure 1. Occasional missing gage data were interpolated from existing gages.

The monthly rates of storage changes were computed by multiplying the differences between two consecutive beginning-of-month levels by the area of the lake given in Table 1 and dividing by the number of seconds in the month.

TABLE I. Lake areas.

Lake	Area, km ²
Lake Superior	82,100
Lake Michigan	57,700
Lake Huron	59,500
Lake St. Clair	1,110
Lake Erie	25,700
Lake Ontario	19,000

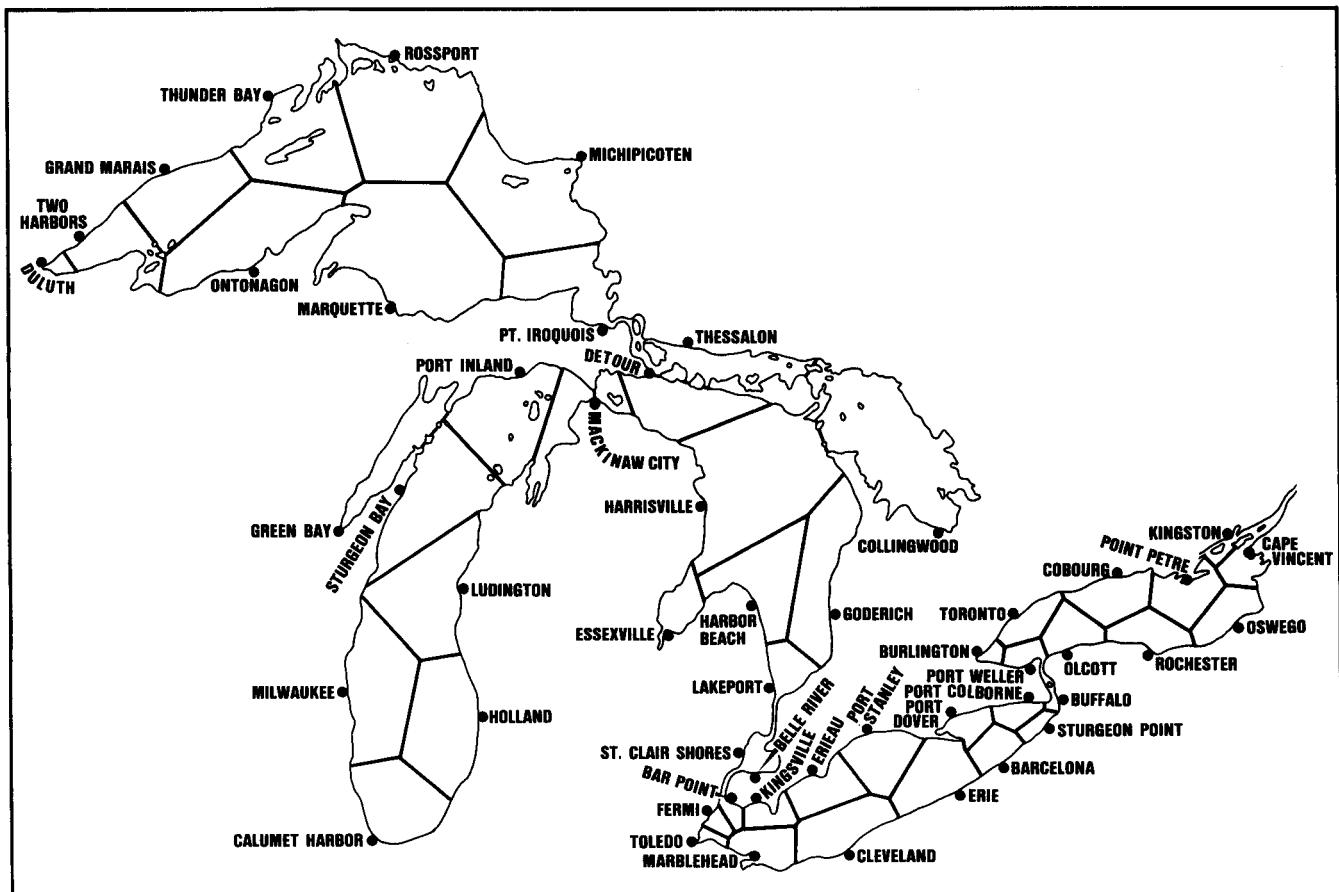

FIG. 1. Gage locations and Thiessen polygon networks.

RESULTS

Crustal Movement

The rate of crustal or gage movement on the Great Lakes has been well documented (Kite and Adamowski 1973, Coordinating Committee 1977) and its effect on Lake Superior studies given by Quinn (1978). In the current study, however, the primary objective is to produce monthly changes in storage, on which the impact of crustal movement is negligible. For example, as depicted in Figure 2, the relative rate of movement between the Mackinaw City and Calumet gates on Lake Michigan is 20 cm per 100 years using yearly mean data. This is equivalent to 0.2 mm per month, a negligible amount. Similar results were found for the other lakes. Thus, no corrections were applied to compensate for crustal movement effects.

Gage Density Analysis

Varying gage networks were analyzed for the 1950-1970 period to determine optimal gage densities. To calculate the time series of lake levels prior to 1949 required additional smaller networks. The Thiessen polygons shown in Figure 1 are for the present time period. The various gage networks used to compute the time series, with their gages and weighting factors, are given in Table 2. The resulting beginning-of-month levels time series for each lake are shown in Tables 3-8.

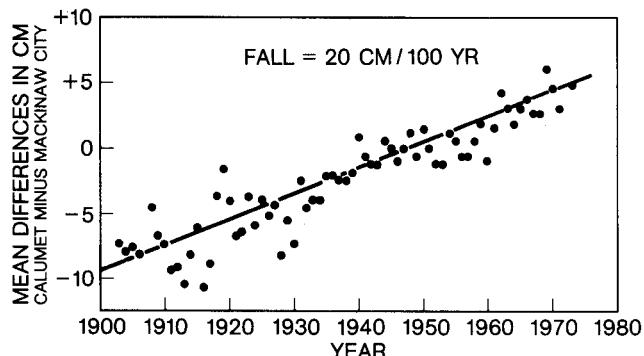

FIG. 2. Plot demonstrating the relative crustal movement between Calumet and Mackinaw City gages. Least squares fit: $Y = 9.42 + 0.198X$.

Thiessen weighting factors and gage networks for other time periods have already been presented for Lake Superior (Quinn and Todd 1974), Lake Michigan (Quinn 1975a), Lake Huron (Quinn 1975b), Lake St. Clair (Kelley 1976), Lake Erie (Quinn and Derecki 1976a), and Lake Ontario (Quinn and Derecki 1976b).

An analysis of the effect of gage network density on reliability of estimated lake level was based on data for the 1950-1970 period. The effect was investigated by comparing beginning-of-month lake levels as computed by various network densities during corresponding time periods. The statistical parameters used in the analysis were the standard deviation about zero, the mean, and the maximum of differences in beginning-of-month levels between two different network densities. TABLE 9. Effect of network size on beginning-of-month levels for Lake Michigan.

Period	No. of observations	Networks compared	Mean Dev* (cm)	Std. Dev* (cm)	Max. Dev* (cm)
1946-1972	324	3 gage vs 4 gage	0	1	5
1950-1972	275	4 gage vs 5 gage	0	1	3
1955-1972	216	5 gage vs 6 gage	0	0	1
1960-1972	312	6 gage vs 7 gage	0	1	2
1965-1972	288	7 gage vs 8 gage	0	0	1

al data observations were added to the 1960-1972 period to make it statistically compatible with the other periods. These additional observations consisted of mid-month and one-third-month levels obtained by the same procedure as the beginning-of-month levels. The results of the analysis of Lake Michigan are presented as an example in Table 9. The table shows good agreement between the networks with the maximum deviation between networks decreasing with increasing density, as is expected. Similar results were found for the other lakes.

Changes-in-Storage

A time series of monthly changes in storage was generated for each lake by the equation

$$\Delta S_t = \frac{(L_{o,t+1} - L_{o,t})A}{86,400 \times D}$$

where

ΔS_t is the change in storage for month t in m^3 / sec

$L_{o,t}$ is the beginning-of-month lake level for month t in m

$L_{o,t+1}$ is the beginning-of-month lake level for month (t+1) in m

A is the lake area in m^2

D is the number of days in month t

86,400 is the number of seconds per day

The resulting monthly rates of change of storage for each lake are available from the publications listed in the preceding section. During the years when the gage density changed, the monthly rates of change in storage may not agree exactly with the recommended beginning-of-month levels. This is because the change in storage was computed from temporally uniform gage densities.

CONCLUSIONS

This study presents a time series of beginning-of-month levels and rates of change in storage of sufficient quality for both scientific and operational studies. Thiessen polygon weighting factors are presented for the current gage networks to enable future extension of the time series.
